### Introduction

Despite the hostile environment of beer, strains of lactic acid bacteria (LAB) have evolved survival mechanisms which may ultimately lead to product spoilage. Identification of beer spoilage organisms (BSOs) has typically been done using culture-based detection methods, with results obtained up to a week after sample processing begins. Furthermore, traditional methods only detect the presence of a particular species but do not necessarily indicate the presence of spoilage genes needed for these organisms to propagate in beer. In contrast, nucleic acid-based detection methods enable rapid detection of BSOs. These methods not only determine the presence of the organism, but also indicate whether or not it has the capability of persisting in the presence of antimicrobial iso-alpha acids derived from hops.

This study evaluates the sensitivity, specificity, and adaptability of the Rheonix Beer SpoilerAlert™ assay, a fully automated sample-to-results multiplexing molecular detection kit. The sample rack, Rheonix CARD® (Chemistry and Reagent Device) cartridges and reagent kit are placed in the Encompass Optimum<sup>™</sup> workstation and all processes required for lysing organisms, extracting nucleic acids, amplifying and detecting target genes, and result analysis are automatically performed without user intervention on the Rheonix workstation. Reagents are dispensed by an onboard robot and liquid is moved via microfluidic pumps and channels within the CARDs. Amplification occurs via the onboard thermocycler and endpoint detection occurs through hybridization to a low-density capture array. Captured targets are detected and analyzed by an onboard camera and imaging software, which provides the user with a report of which genes and/or organisms are detected. Four individual samples are analyzed per CARD, with 6 CARDs per run, resulting in up to 24 independent samples analyzed in 5 hours, with minimal hands on time.

## Beer SpoilerAlert™ Workflow

Simple, rapid, multiplexed microorganism detection system using the Encompass Optimum™ workstation • Fully integrated sample prep and detection - True walk-away capability Minimal hands-on time

Can multiplex up to 22 individual targets

Throughput of 24 samples

Sample Collection

~ 15 minutes **Hands-on Time** 

**5 Hour Runtime Fully Automated** 

detection

The Rheonix Beer SpoilerAlert™ assay targets four distinct sequences enabling rapid detection of lactic acid bacteria and four sequences detecting hop resistance genes. Furthermore, the assay also contains targets for three yeast sequences to detect the following strains: Saccharomyces cerevisiae (brewer's yeast), S. cerevisiae var. diastaticus and Brettanomyces bruxellensis. This is useful to detect crosscontamination by yeast purposefully used to make beer (S. cerevisiae, B. bruxellensis), while also detecting the spoilage yeast S. cerevisiae var. diastaticus. The presence of *S. cerevisiae* var. diastaticus is of particular concern due to its genetic homology with brewer's yeast and typically remains undetectable until spoilage occurs.

## Materials & Methods

Strains, Media and Culture Conditions Microorganisms were obtained from The Beer Research Institute, ATCC, DSMZ, National Collection of Yeast Cultures, local craft breweries and the United States Department of Agriculture, maintained as stock cultures in 20% glycerol at -70°C and propagated as per provider instructions. Lactic acid bacteria were grown using MRS supplemented with beer (B-MRS) and yeast were grown using YM (DIFCO). B-MRS was prepared with filtered clear beer. B-MRS agar plates were prepared by adding filtered beer to autoclaved MRS agar, to a final concentration of 0.5xBeer/0.5xMRS. Lactic acid bacteria were incubated at 30°C, under a 10% CO<sub>2</sub> atmosphere, while yeasts were incubated aerobically at 25°C.

Analysis of Samples on the Encompass Optimum™ Workstation o validate target specificity of the Rheonix Beer SpoilerAlert™ assay using the Encompass Optimum™ workstation, overnight cultures were grown in liquid media under appropriate conditions. Cultures were counted using a Cellometer X2 (Nexcelom) confirmed with plate counts, and diluted accordingly in either media or buffer to desired concentration. Samples were run on the workstation, and the results were analyzed through an automated software report.

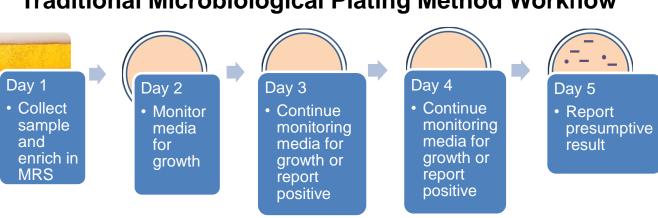

Limit of Detection (LOD) Cultures were first diluted in phosphate buffered saline (PBS), followed by dilutions in filtered beer to obtain suspensions ranging from 10<sup>1</sup> to 10<sup>5</sup> CFU/mL. Each dilution was analyzed directly on the Encompass Optimum (2 mL per sample tube). Ten mL of each dilution was then filtered through a 47 mm, 0.45 µm filter. Cells were collected off the filter in 2 mL of PBS and analyzed on the workstation.

Minimum Enrichment Inoculum (MEI) Cultures were diluted in B-MRS to obtain suspensions ranging from 10<sup>0</sup> to 10<sup>3</sup> CFU/mL. Ten mL of each dilution were filtered through a 47 mm, 0.45 µm filter. The filter was then placed in a 60 mm Petri dish with 2 mL B-MRS, and incubated for 18 and 24 hours at 30°C under 10% CO<sub>2</sub> treatments. After 18 hours, both sets of samples were removed from the incubator he enriched filters were scraped using cell scrapers and suspensions were transferred to sample tubes. In parallel, both sample sets were analyzed on the workstation. The samples were allowed to incubate for an additional six hours and analyzed again on the workstation.

**Environmental Sampling** Overnight cultures of *Lactobacillus buchneri* and 10<sup>4</sup> CFU/mL. For each dilution, 10 x 10 μl were applied onto a sterile stainless steel surface, allowed to attach for 30 minutes, and then collected with a swab prewetted with MRS. Swabs were transferred immediately into MRS in sample tubes and were incubated for 24 hours at 30°C and 10% CO<sub>2</sub> modified atmosphere. In addition, various locations in a brewery were swabbed, with samples taken from various locations in the plant including tanks, valves, surfaces, tubes, and drains. Swabs were treated similarly, with enrichment immediately in MRS broth.

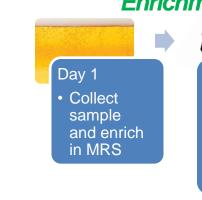

Targets detected with the Beer SpoilerAlert™ Assay: Key for filters					
RS	Assay reference spot				
Targets amplified by Master Mix 1					
MM1	Control for PCR Master Mix 1				
PC	Target found specifically in <i>Pediococcus claussenii</i>				
LB	Lactobacillus brevis				
SC	Saccharomyces cerevisiae				
DIA	Saccharomyces cerevisiae variant diastaticus				
BRETT	Brettanomyces bruxellensis				
Targets amplified by Master Mix 2					
MM2	Control for PCR Master Mix 2				
PED	Target found in all currently sequenced <i>Pediococcus</i> species				
LABS	Plasmid biomarker present in strains of various lactic acid bacteria (LAB)				
HORA	Hop resistance gene, horA, found on plasmids in various LAB				
HORC	Hop resistance gene, horC, found on plasmids in various LAB				
BSRA	Hop resistance gene, bsrA, found in P. claussenii				
BSRB	Hop resistance gene, bsrB, found in P. claussenii				

### **Traditional Microbiological Plating Method Workflow**

# Rheonix Beer SpoilerAlert™ Assay Workflow

#### Results

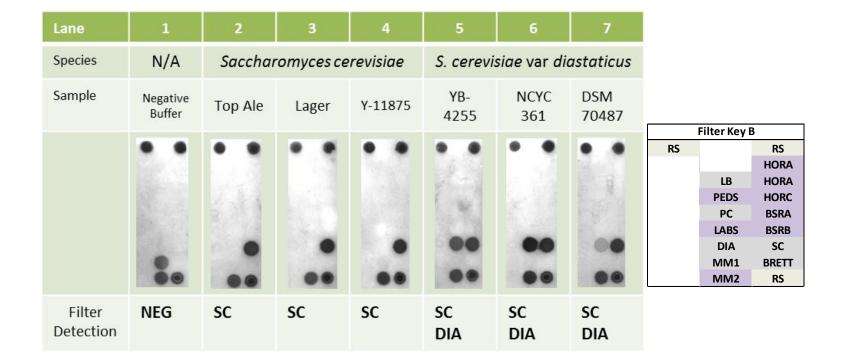

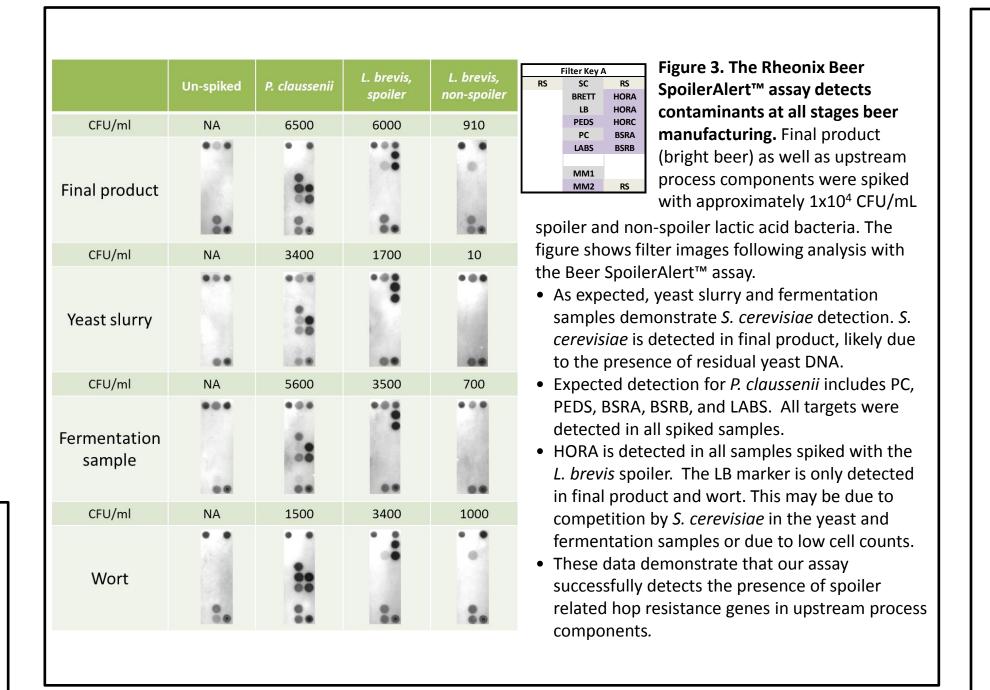

Figure 1. The Rheonix Beer SpoilerAlert™ assay can distinguish Saccharomyces cerevisiae variant diastaticus from S. cerevisiae. Different strains of yeast were spiked into Rheonix collection buffer at a concentration approximately 1x10<sup>7</sup> CFU/mL and analyzed using the Encompass Optimum™ workstation. Three strains of brewers yeast (lanes 2-4) are distinguishable from three independent *S. cerevisiae* var. diastaticus (lanes 5-7). The key on the right of the figure indicates probe orientation on the filters.

	Limit of Detection (LOD)  CFU/mL		Minimum Enrichment Inoculum (MEI) Total CFU inoculum/ 2 mL			
Microorganism tested	Direct	Filtered	Direct		Filtered	
			18 h	24 h	18h	24 h
Lactobacillus buchneri	1x10 <sup>4</sup>	5x10 <sup>4</sup>	10	10	10	1
Pediococcus claussenii	1x10 <sup>4</sup>	5x10 <sup>3</sup>	10	1	10	10
Brettanomyces bruxellensis	1x10 <sup>5</sup>	5x10 <sup>4</sup>	100	100	100	100
Saccharomyces cerevisiae var. diastaticus	1x10 <sup>4</sup>	5x10 <sup>4</sup>	ND	10	10	10

**Figure 2. The limit of detection and minimum enrichment inoculum.** The LOD and MEI are presented for Lactobacillus buchneri (LB), Pediococcus claussenii (PC), Brettanomyces bruxellensis (BB), and Saccharomyces cerevisiae var. diastaticus (SC/DIA). The data demonstrate LODs approximated to 1X10<sup>4</sup> CFU/mL for the LAB and SC/DIA, and 1X10<sup>5</sup> CFU/mL for BB. A minimum inoculum of 10 CFU in a final volume of 2 mL is sufficient to detect LB, PC and SC/DIA after 18 hours, while 100 CFU is required to detect BB. For LB the inoculum can be decreased to 1 CFU/2 mL when the sample is allowed to enrich for 24 hours. The LOD and MEI are defined when 100% of replicates are positive in a single experiment, however detection at

lower levels has been observed in multiple experiments. (ND=not determined)						
Sample Handling Procedure	Definition					
Direct	Suspension of microorganisms in beer at the concentration indicated					
Filtered	Sample concentrated by filtration, re-suspended in PBS					
Enriched/Direct	Sample enriched in B- MRS (bacteria) or YM (yeast) in sample tubes					
Enriched/Filtered	Sample concentrated by filtration and enriched in B-MRS or YM					

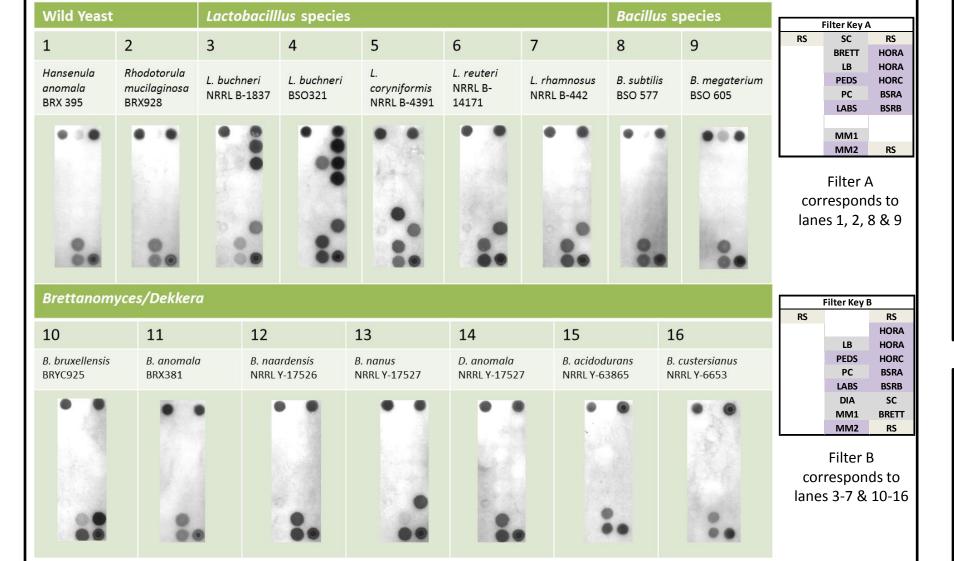

Figure 4. Assay Specificity. Assay specificity was confirmed via testing of potentially crossreacting organisms. Two wild yeast, Hansenula anomala, and Rhodotorula mucilaginosa were tested for potential cross-reactivity with *B. bruxellensis* and *S. cerevisiae*. Two *Bacillus* species were tested for potential cross-reactivity with *Lactobacillus* and *Pediococcus*. Various nonbruxellensis species were tested for cross-reactivity with B. bruxellensis. All non-targeted species tested negative demonstrating no cross-reactivity, and thus present minimal risk for false positives to be called with these organisms. Our assay currently does not have a generic *Lactobacillus* marker, and identification of *Lactobacillus* species is dependent on the presence of the plasmid associated markers, horA, horC, and LABS. Additionally, there is a marker specific for L. brevis that demonstrates similarity, but not identity, with other *Lactobacillus* species. Detection of the LB probe is potentially expected at very high concentrations of non-brevis species that demonstrate significant homology. The data demonstrate detection of the LB probe in L. buchneri, but not in L coryniformis, L. reuteri, or L. rhamnosus. In addition, plasmid associated targets are seen in L. buchneri and L. coryniformis.

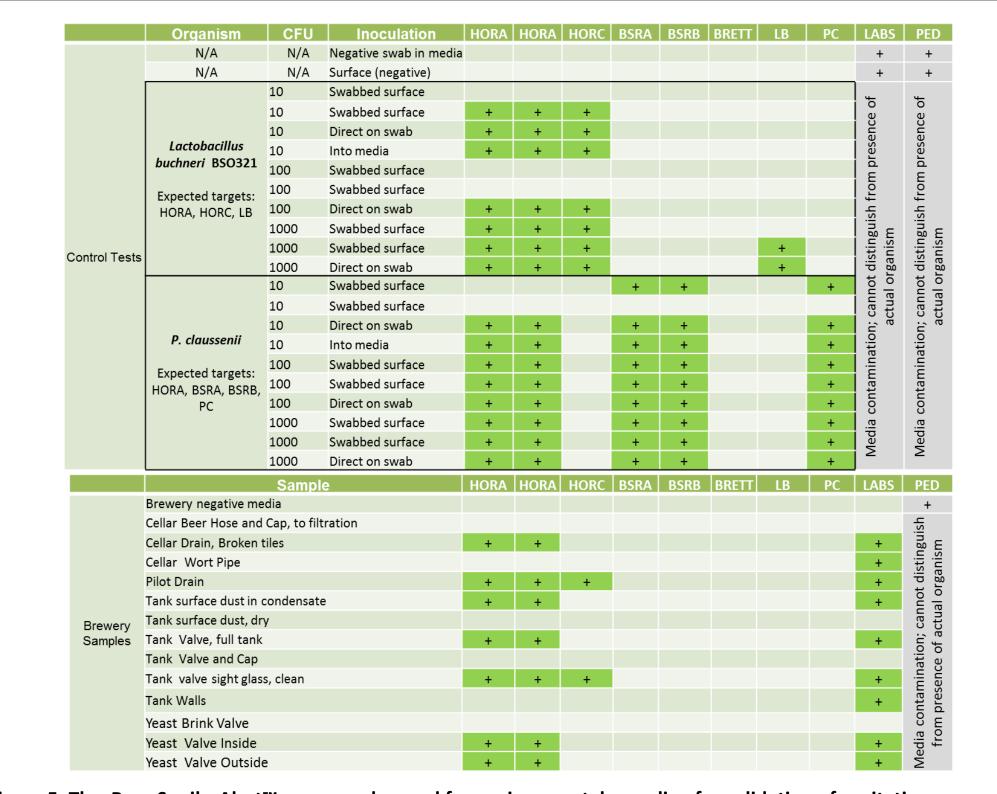

Figure 5. The Beer SpoilerAlert™ assay can be used for environmental sampling for validation of sanitation **procedures.** Control experiments were performed with known concentrations of microorganisms. Swabs containing MRS were used to collect **Swabbed surface** samples. **Into media** samples contain a known concentration of spoilers added directly to the media, and **Direct on Swab** samples were obtained by adding microorganisms directly onto swabs. Control experiments illustrate detection of all anticipated genomic and plasmid targets. Unsurprisingly, brewery samples showed detection of SC in all samples tested (data not shown). In contrast, there was no evidence of *P. claussenii* since PC, BSRA, and BSRB were not detected; L. brevis was also not detected. However, the three plasmid targets including the horA and horC hop resistant genes, as well as the lactic acid bacteria marker (LABS) found in some lactic acid bacteria were detected. The presence of yeast DNA in commercial MRS media results in "contamination" of samples, where PED and LABS are sometimes detected in our negative controls.

# **Summary & Conclusions**

- The minimum inoculum required for detection following enrichment for all target organisms is approximately  $\leq 10$  CFU/mL. The limit of detection is  $10^4$  CFU/sample before enrichment.
- The assay is specific in its detection of B. bruxellensis, S. cerevisiae, and S. cerevisiae var. diastaticus. This is useful to detect cross-contamination by yeast purposefully used to make beer (S. cerevisiae, B. bruxellensis), while also detecting the spoilage yeast S. cerevisiae var. diastaticus. The presence of S. cerevisiae var. diastaticus is of particular concern due to its close genetic homology with brewer's yeast.
- All Pediococcus species are detected, with an additional target to specify Pediococcus claussenii.
- The assay is adaptable in its ability to detect these microorganisms in a variety of matrices including wort, yeast slurry, fermentation, final product, and environmental samples.
- While the assay distinguishes between spoiler and non-spoiler Lactobacillus species, not all Lactobacillus species will be detected unless closely related to L. brevis and/or contain the targeted plasmid associated sequences.
